

The Performance of Actively and Passively Managed Swiss Equity Funds

Manuel Ammann and Michael Steiner*

February 2008

Abstract

Using a Switzerland-specific Carhart (1997) model, we study the risk-adjusted performance of actively and passively managed funds investing in Swiss stocks from 1989 to 2007. We also compare the performance of actively managed funds to passively managed funds instead of comparing them to a theoretical index. For a sample of 160 funds with 13'672 monthly observations we find that active as well as passive funds significantly underperform indices on an aggregated basis. However, active large-cap funds significantly underperform and active Small-&Mid-Cap-funds significantly outperform the index. Further, we find that the average manager of an active Swiss equity fund systematically overweights small-cap, value, and low-momentum stocks. When directly comparing active to passive funds, active funds significantly underperform by -1.1% p.a. on average. Finally, active funds perform better before the millennium than thereafter. This robust result supports the hypothesis of ongoing efficiency increases in the Swiss stock market.

1. Introduction

There are two schools of thought with regard to security selection. The first one argues that managers should actively choose securities with the objective to outperform the benchmark. In contrast, the second argues that investors should invest passively within each asset class and devote their investment resources to making high-level asset allocation decisions. Performance analyses contribute to the evaluation of the superior approach. However, most of the existing studies measure the performance in comparison to a theoretical benchmark index. But as passive investing is not cost-free this is not the best way of analysing the performance of actively managed mutual funds. They should therefore be compared to index funds.

We add a Swiss analysis to the active-passive debate and to the scarce evidence on the performance of Swiss equity mutual funds. To this end, we study the performance of 160 mutual funds investing in Swiss stocks from January 1989 to March 2007 using a Switzerland-specific Carhart (1997) model.

Our contribution to the existing literature is threefold:

1. We substantially extend the Swiss studies of Lhabitant (2001), von Wyss (2001), Lhabitant (1995), and Zimmermann and Zogg-Wetter (1992) by applying an advanced performance measurement methodology, by analysing a larger sample with a reduced survivorship bias, by including the years 2000 to 2007, by analysing factor loadings and by checking the robustness of the results in subgroups and subperiods of the sample.
2. We directly compare actively and passively managed Swiss equity funds. Thereby, we apply a convenient methodology based on the Switzerland-specific Carhart (1997) model developed by Ammann and Steiner (2008). To the best of our knowledge, this is the first time this methodology of directly comparing active and passive funds within the Carhart (1997) framework is applied.
3. We analyse the performance of passive Swiss equity funds. This has only become possible due to the rise of Swiss index funds in the recent years.

The debate on whether active investing is better than indexing gained in importance in the last years. Malkiel (1995) looks at the returns of US mutual funds from 1971 to 1991 and compares them with two benchmarks, the Wilshire 5000 Index and the S&P 500 Index. He finds that indexing outperforms actively managed funds. Jensen (1968), Lehmann and Modest (1987), Elton, Gruber, and Blake (1996), Gruber (1996), Carhart (1997), Wermers (2000), Malkiel (2003), Deaves (2004), Bogle (2005), Malkiel (2005) and Costa, Jakob, and Porter

(2006) find that actively managed investment funds on average underperform their benchmarks on a risk-adjusted basis between 80 and 320 basis points per annum.

All of the previously mentioned studies compare actively managed funds directly to theoretical indices. Bogle (1998) started a new way of comparing active and passive investing. He compares the performance of US equity investment funds with the performance of Standard & Poor's index funds from 1992 through 1997. He concludes that the average return for all the funds in the index group is 1.4 percentage points above the average return for the actively managed funds. Minor (2001) moves the five-year data series from Bogle (1998) two years backwards (1990 through 1994) and finds that actively managed funds outperformed their peers during this period of time. Bogle (2002) responds by analysing a ten-year period from 1991 to 2001. He shows that indexing delivers on average a higher average return. Fortin and Michelson (2002) find that index funds on average outperform actively managed funds. However, Minor (2003) counters by showing that results are not as clear-cut. For a twenty-year period ending December 2001 he concludes that actively managed US funds have essentially the same net-of-fees return as a comparable index fund, with Small Cap Funds performing better than Large Cap Funds. Reinker and Tower (2004) find that it is the time span of the observed returns that determines which instrument delivers superior returns. However, over the whole period actively managed funds outperform their passive peers. Kizer (2004) extends Reinker and Tower's (2004) study and finds that the difference in the returns of the active and index portfolios is attributable largely to the value and size premiums. Overall, these US-studies show that the answer whether active or passive investing performs better is not as clear-cut as often asserted.

However, all the cited studies rely on data for US equity funds. There are few studies analysing the fund universe in Europe and Switzerland. Bams and Otten (2002) give a comprehensive overview on earlier European research on mutual fund performance and provide results on France, Germany, Italy, Netherlands and UK from 1991-1998. The study, based on the Carhart (1997) model, shows that on average the analysed actively managed funds outperform the respective index. Griesse and Kempf (2003) provide a study for German equity mutual funds. For the period from 1980 to 2000 they find that index funds significantly outperform actively managed funds.

In Switzerland, equity mutual fund performance analysis starts with the paper of Zimmermann and Zogg-Wetter (1992). They analyse the performance of six Swiss equity funds during the time period from 1984 to 1990. They conclude that there is no systematic

outperformance of actively managed funds. Lhabitant (1995) continues by analysing the Sharpe- and Treynor-ratios of 17 Swiss equity mutual funds from July 1983 to June 1994. He observes that on average the funds fail to beat the market index. Von Wyss (2001) analyses 24 Swiss equity mutual funds from 1995 to 1999, based on a single (market-)factor model and various ratios. 75% of the alphas in his study are negative, with no significantly positive alpha. Finally, Lhabitant (2001) analyses 60 funds from 1977 to 1999. He finds an average, not statistically significant Jensen alpha of -1.78% p.a. Looking at the single funds, not one out of the nine positive alphas is significant.¹

Overall, the studies present evidence that actively managed funds are not able to systematically deliver a better performance than their corresponding benchmarks. However, a few studies show that this result is not robust.

The remainder of the paper is structured as follows: Section 2 describes our data and Section 3 explains the methodology applied. In Section 4 the results of the empirical study are presented. Section 5 summarizes our key findings.

2. Data

To study the performance of Swiss equity mutual funds we construct a database consisting of the monthly total returns of 160 mutual funds exclusively investing in Swiss equities.² The end-of-month data available covers the time period from January 1989 to March 2007. The continuously compounded total return data is calculated in Swiss Francs and on a NAV basis.³ Overall, the database consists of 13'672 monthly return observations, which are on average approximately 85 observations (7 years and 1 month) per fund. As there exists no complete register where data from Swiss funds are listed, we used the following sources to build our database: Swiss Exchange, Swiss Funds Association, Swiss Federal Banking Commission, Swiss Association of Investment Companies, Feri Rating & Research GmbH, Micropal, Lipper, Bloomberg, Datastream and Morningstar. Our database does not have information on fund expenses, fund size, or fund holdings as those are only partly or not available and because their influence on performance has been analysed extensively in many

¹ Ammann, Haller and von Wyss (2002) analyse the performance of six Swiss investment trusts in relation to the benchmarks. The main conclusion of their work is that during the time period from 1996 to 2002 the six analysed trusts do not bring statistically significant out-/underperformance compared to the benchmark.

² ETFs (Exchange traded funds) are included.

³ Dividends have been assumed to be reinvested. Load charges and redemption fees (if any) are ignored. We have calculated the dividend-adjusted prices for 55 funds. A small bias could be induced by a different fiscal treatment of funds reinvesting the dividends and funds which do not pay out dividends. However, this bias is small and was therefore not taken into account.

earlier studies. Therefore, this has not been further analysed in our study. The split of the database into active and passive funds, into retail and institutional funds, into SPI-, SMI- and Small&Mid-Cap-funds, and into surviving and non-surviving funds is described in Table 1. This categorization is strictly based on the information provided by the fund management. Further, Table 2 presents the number of funds in the database at the end of each calendar year. This table shows that in the early years of the study the number of passive funds is small.

Concerning the classification by benchmark, funds with similar benchmarks have been aggregated into one group based on the correlations of the benchmarks: Funds that reported the SPI or the UBS 100 index as their benchmark are allocated to the group “SPI-funds”, funds with the SMI or the MSCI Switzerland as their benchmark are allocated to the “SMI-funds” and those reporting Swiss Small- and Mid-Cap stocks as their investment universe are allocated to the “Small&Mid-Cap-funds”. Tests not reported here confirmed the classification of the funds.⁴

Table 1: Breakup of the funds analysed by benchmark, client segment, activity, and survival

Fund Benchmark	Fund Category	Active Funds			Passive Funds			Total
		Sur-viving	Non-sur-viving	Total	Sur-viving	Non-sur-viving	Total	
SPI	Retail	49	5	54	3	0	3	57
	Institutional	7	3	10	4	0	4	14
	Total	56	8	64	7	0	7	71
SMI	Retail	18	6	24	7	0	7	31
	Institutional	6	3	9	3	1	4	13
	Total	24	9	33	10	1	11	44
Small & Mid Cap (SMC)	Retail	25	6	31	1	0	1	32
	Institutional	13	0	13	0	0	0	13
	Total	38	6	44	1	0	1	45
Total		118	23	141	18	1	19	160

Table 1 shows a breakup of the mutual funds analysed in this study. The funds have been categorized by their benchmark (SMI, SPI, Small & Mid Cap), by their client segment (retail/institutional), by their level of activity (active/passive), and by their survival (surviving/non-surviving).

⁴ Tracking errors and correlations in comparison to the appropriate benchmark indices confirm the validity of the classification of the single funds.

Table 2: Yearly number of mutual funds analysed

Year	Active Funds	Passive Funds	All Funds
1989	5	1	6
1990	8	1	9
1991	11	1	12
1992	14	1	15
1993	17	1	18
1994	22	1	23
1995	31	1	32
1996	45	3	48
1997	56	4	60
1998	60	5	65
1999	72	6	78
2000	82	8	90
2001	101	10	111
2002	103	10	113
2003	106	14	120
2004	119	17	136
2005	124	19	143
2006	119	18	137
2007	118	17	135

Table 2 shows the number of Swiss equity mutual funds analysed in this study. The numbers represent funds with observations at the end (December) of the respective year. For the classification into active and passive is based on the declaration by the fund manager.

3. Methodology

This section explains how the fund database is analysed. As we have no information on portfolio holdings, we estimate the performance of the funds using the Carhart (1997) regression model. As the Carhart factors are country-specific, Ammann and Steiner (2008) develop and describe the factors for the Switzerland-specific Carhart model. We apply their Switzerland-specific four-factor model to estimate the performance of the Swiss equity mutual funds. Formally, this model is estimated as:

$$R_{it} - R_{ft} = \alpha_{iT} + \beta_{1iT}RMRF_t + \beta_{2iT}SMB_t + \beta_{3iT}HML_t + \beta_{4iT}UMD_t + e_{it}$$

where $R_{it} - R_{ft}$ is the excess return of mutual fund i over the risk-free rate (CHF call money rate provided by Factset) at time t . $RMRF_t$ is the excess return of the benchmark portfolio over the risk-free rate (CHF call money rate provided by Factset) at time t and SMB_t , HML_t and UMD_t are the returns of zero-investment factor-mimicking portfolios for size, value, and

momentum at time t .⁵ Finally, the intercept α_i is our performance measure, estimating the fund performance relative to the four-factor benchmark. Time series for the Switzerland-specific SMB, HML, and UMD factors are provided by Ammann and Steiner (2008). Their paper describes in detail the construction, characteristics, and robustness of these factors.

By means of panel regressions, this four-factor measurement methodology is applied to all performance evaluations in this paper. In a first step, the benchmark portfolio is an index. The performance of passive and active funds in various subgroups and during different subperiods is evaluated against this theoretical benchmark portfolio. Table 3 gives the definitions of the subgroups and subperiods analysed. In a second step, actively managed funds are tested against equally weighted benchmark portfolios constructed from the passively managed funds in our database. The benchmark portfolio is therefore an investable portfolio of tradable passive funds. Again, various subgroups during different subperiods are analysed. The alphas resulting from these panel regressions are a direct estimate of how the actively managed Swiss equity mutual funds performed in comparison to their passively managed peers. To the best of our knowledge, this is the first time that this appealing methodology is applied to directly comparing active and passive funds. In a third step, SPI-, SMI-, and Small&Mid-Cap-Funds are analysed separately against corresponding equally weighted benchmark portfolios of passive funds. The robustness of the results is tested in different subgroups and during different subperiods.

As several studies have shown before, the survivorship bias could potentially influence the results. If the records of non-surviving funds – most probably the worst performing ones – were not included, a potential study could only take into account the slightly higher performance of the surviving ones. Such a study would suffer from a survivorship bias and not reflect the true picture of the average fund performance. The survivorship bias is well documented for US equities. Grinblatt and Titman (1989) find a survivorship bias between 10 and 30 basis points on a yearly basis (data from 1975 to 1984). Brown and Goetzmann (1994) find a bias of around 20 to 80 basis points per year (data from 1976 to 1988). The survivorship bias in Malkiel (1995), Elton, Gruber, and Blake (1996), Gruber (1996) and Carhart, Carpenter, Lynch, and Musto (2002) ranges from 0.07% to 2.1% per annum, dependent on the calculation method and weighting scheme used.

⁵ SMB stands for “Small Minus Big” (size; measured by the market capitalization), HML for “High Minus Low” (value; measured by the book-to-market ratio) and UMD for “Up Minus Down” (momentum; measured by the one-year past return). UMD is also known as WML (“Winners Minus Losers”) in the literature.

Table 3: Definitions of the subgroups and subperiods analysed

Panel 1: Subgroups		
Classification Criterion	Subgroup Name	Definition
None	All funds	All 160 active and passive funds.
	Activity	
Activity	Active funds	All funds with an active investment strategy. Overall, there are 141 active funds.
	Passive funds	All funds with a passive investment strategy. Overall, there are 19 passive funds.
Client segment	Retail funds	All funds that are distributed with a focus on retail investors. Overall, there are 120 retail funds.
	Institutional funds	All funds that are distributed to institutional investors only. Overall, there are 40 institutional funds.
Survival	Surviving funds	All funds that still existed at the end of the observation period (March 2007). Overall, there are 136 surviving funds.
	Non-surviving funds	All funds that were liquidated or merged before the end of the observation period (March 2007). Overall, there are 24 non-surviving funds.
Investment universe	SPI-funds	Funds that reported the SPI or the UBS 100 index as benchmark. Overall, there are 71 SPI-funds.
	SMI-funds	Funds that reported the SMI or the MSCI Switzerland as benchmark. Overall, there are 44 SMI-funds.
	Small&Mid-Cap-funds (SMC-funds)	Funds that focus their investments on Small- and Mid-Cap stocks only. Overall, there are 45 SMC-funds.
Panel 2: Subperiods		
Classification Criterion	Subperiod name	Definition
None	All periods	All observations (January 1989 - March 2007).
	Century	
Century	Early	All observations before the millenium (January 1989 - December 1999).
	Late	All observations after the millenium (January 2000 - March 2007).
Stock market condition	Bear	All observations during the bear market from September 2000 - March 2003.
	Bull	All observations during the bull market from April 2003 - March 2007.

Table 3 defines the subgroups (Panel 1) and subperiods (Panel 2) analysed. In the paper, combinations of these subgroups and subperiods are studied as well. The categorization is strictly based on the declaration made by the management of the funds.

Table 4 shows an estimate of the survivorship bias based on our Switzerland-specific database. These numbers are in line with the literature described above. We therefore conclude that our sample is not affected importantly by the survivorship bias.⁶ This is an improvement over earlier Swiss studies, which suffered from the survivorship bias.

Table 4: Estimation of the survivorship bias for the active funds in the database

Calculation method	Δ Alpha (annualized)	
	January 89 to March 07	January 00 to March 07
Alpha surviving active funds - Alpha all active funds	0.07%	0.34%
Alpha surviving active funds - Alpha non-surviving active funds	0.52%	2.40%

Table 4 shows an estimation of the survivorship bias based on our database. Two measures that estimate the bias are calculated for all active funds in the database. The first is the difference of the annualized alphas of the surviving funds and all (surviving+non-surviving) funds, the second is the difference of the annualized alphas of the surviving funds and the non-surviving funds. These Δ Alphas are calculated for two different time periods (January 1989 - March 2007; January 2000 - March 2007). All alphas are calculated with panel regressions based on the Switzerland-specific Carhart (1997) model presented by Ammann and Steiner (2008). The benchmark portfolio is the benchmark-equivalent portfolio of passive funds.

4. Empirical Results

This chapter studies the performance of the funds in our database by means of the Switzerland-specific Carhart model described above. We start with aggregated samples in comparison to the index and proceed by breaking it down into more detail and by performing comparisons to passive funds. For the regressions, we always use the corresponding index or passive funds as benchmark portfolio, meaning that we compare SPI-funds to the SPI or passive SPI-funds, SMI-funds to the SMI or passive SMI-funds, and SMC-funds to the SMIM or passive SMIM-funds. Thereby, we maximise the explanatory power of the regression results.

The first part (Tables 5 to 13) measures the performance against corresponding indices. Tables 5 and 6 start with an aggregated overview. Tables 7 to 9 (Section 4.1) analyse the performance of passive funds compared to their reference index. Tables 10 and 11 (Section

⁶ Due to the fact that we had no access to data from both surviving and non-surviving funds we may not ultimately rule out that there is a survivorship bias. However, due to the results in Table 4 (showing that our sample is in line with samples that ultimately excluded the survivorship bias) we assume that our sample is survivorship bias free.

4.2) measure the performance of active management in comparison to the corresponding index. Tables 12 and 13 (Section 4.3) complete the first part by showing the distribution of the alphas (in comparison to corresponding indices) and the factor loadings of the regressions for all 160 single funds. The second part (Tables 14 to 18) measures the performance of the active funds in comparison to the passive funds. Tables 14 and 15 (Section 4.4) give an aggregated overview. Section 4.5 looks at more detail: Table 16 analyses the performance of the active SPI-, Table 17 of the active SMI- and Table 18 of the active Small&Mid-Cap-funds in comparison to their passive counterpart.

Table 5 allows drawing first conclusions. Comparing all funds during the whole period to their corresponding index, we find a significant underperformance of -0.4% p.a. on the highest aggregated basis. All active funds show an underperformance of -0.4% p.a. as well, with significance at the 10%-level. All passive funds, however, underperform their corresponding index by a highly significant -0.8% p.a.

Further, Table 5 shows the factor loadings of the regressions. As expected from a theoretical point of view, we find significant loadings for the active funds, but no loadings except the market beta significantly different from zero for the passive funds. Overall, the active funds show a highly significant, positive loading for the size factor and a highly significant, negative loading for the momentum factor. The value factor has a positive loading, significant at the 10% level. These factor loadings show that on average managers of active Swiss equity funds systematically overweight small-cap, value, and low-momentum stocks in comparison to their benchmark. Further, the significant difference of the market beta of active funds from 1 indicates that on average the funds are either holding low-beta stocks or are not fully invested in equities but hold a strategic proportion of cash.

Table 6 breaks these results down into subperiods. We find that the performance of the active funds is better in the “Early” than in the “Late” time period.⁷ A possible interpretation could be that financial markets became more efficient during the last 18 years. Consequently, active funds had increasing difficulties to perform well. The performance of passive funds remains stable during these two periods. However, results for passive funds during the “Early” period have to be interpreted with care as the number of passive funds is small during this period.

Further, Table 6 indicates that active and passive funds perform better during the “Bear” market than during the “Bull” market. Thus, market direction seems to influence the risk-

⁷ The subgroups and subperiods are described in Table 4.

adjusted performance of fund managers. This observation is in line with the findings of Costa, Jakob, and Porter (2006) for US funds.

Finally, the last column of Table 6 shows the differences between the alphas of the subgroup of all active and all passive funds and its significance⁸. All differences are in favour of the active funds, but none are significant. Thus, no conclusion is possible whether active or passive investing actually performs better.

In sum, Tables 5 and 6 show five important findings. First, we observe a significant underperformance of active and passive funds in comparison to their corresponding index. Second, no conclusion on the superiority of the performance of active or passive investing may be drawn so far as the difference in the alpha is not significant. Third, active funds performed better in the “Early” than in the “Late” time period, which could be due to

Table 5: Annualized Performance of the funds and regression factor loadings

	Subgroup	All Funds	All Active Funds	All Passive Funds

Table 5 shows the estimation of the performance of the groups of all funds, of all active funds, and of all passive funds compared to their corresponding benchmark index (benchmark portfolio). The performance is measured by the annualized Alpha from panel regressions of the Switzerland-specific Carhart (1997) model. The risk premiums for the size, value, and momentum factors are provided by Ammann and Steiner (2008). The Alphas are calculated for the whole time period. In addition to the performance, the Alpha's t-statistic, the number of observations, the adjusted R-squared of the regressions, and the factor loadings and their t-statistics are shown. The asterisks indicate significance at the 1%-level (***), 5%-level (**), and 10%-level (*).

⁸ In this paper, the significance of differences of alphas is tested by means of a t-test.

increased market efficiency. Passive funds, however, showed stable performance during the “Early” and the “Late” time period. Fourth, active and passive managers performed better in “Bear” markets than in “Bull” markets. Fifth, the factor loadings show that on average managers of active Swiss equity funds overweight small-cap, value, and low-momentum stocks in comparison to their benchmark. The following sections will validate these observations and test their robustness.

Table 6: Annualized Performance of the funds compared to their benchmark index

Table 6 shows the estimation of the performance of the groups of all funds, of all active funds, and of all passive funds compared to their corresponding benchmark index (benchmark portfolio). The performance is measured by the annualized Alpha from panel regressions of the Switzerland-specific Carhart (1997) model. The risk premiums for the size, value, and momentum factors are provided by Ammann and Steiner (2008). The Alphas are calculated for different time periods that are described in Table 3. In addition to the performance, the Alpha's t-statistic, the number of observations, and the adjusted R-squared of the regressions are shown. The last column of the table shows the differences of the alphas between active and passive funds, testing the significance of these differences by means of a t-test. The asterisks indicate significance at the 1%-level (***), 5%-level (**), and 10%-level (*).

4.1 Passive funds vs. index

Tables 7, 8, and 9 show the results of the performance analysis of various subgroups of passive Swiss equity funds. The performance of the passive funds is measured against their corresponding index.

For all subgroups of passive funds analysed in Tables 7 and 8, observations one (underperformance), three (no evidence for a performance difference during the “Early” and “Late” time period) and four (better performance during “Bear” period than during “Bull” period) from the last paragraph are confirmed. Observations two and five (concerning active funds) can not be further validated as these tables show results for passive funds only.

As Table 7 shows, both passive SPI- and SMI-funds underperform their corresponding index significantly by -0.5% p.a. and -1.0% p.a. respectively. We find an underperformance for all subperiods but the “Bear” period where the alphas are close to zero for both subgroups. The same is true for the passive institutional and retail funds in Table 8: Both significantly underperform, with the exception of the “Bear” period. The risk-adjusted performance of the passive Small&Mid-Cap-Fund is substantially negative as well. However, this result has to be interpreted with care as there is only one fund with just a few observations. Last but not least, Table 9 shows that on average the passive SMI-ETF’s underperform the SMI as well, although this result is not significant. However, this result has to be interpreted with care too as there are only three funds and the number of observations is limited.

The analysis of the subgroups of the passive SMI-, SPI- and SMC-funds in Table 7 provides one further finding. Passive SPI-funds show a smaller underperformance than passive SMI- or SMC-funds. However, as a t-test not reported here showed this result is not statistically significant. Nevertheless, this could be a helpful hint for investors looking for an efficient passive Swiss stock market investment.

Table 7: Annualized Performance of passive funds compared to their benchmark index

Subgroup		All Passive Funds	All Passive SPI- Funds	All Passive SMI- Funds	All Passive SMC- Funds

Table 7 shows the estimation of the performance of the groups of all passive funds, of all passive SPI-funds, of all passive SMI-funds, and of all passive SMC-funds (Small&Mid-Cap-funds) compared to their corresponding benchmark index (benchmark portfolio). The performance is measured by the annualized Alpha from panel regressions of the Switzerland-specific Carhart (1997) model. The risk premiums for the size, value, and momentum factors are provided by Ammann and Steiner (2008). The Alphas are calculated for different time periods that are described in Table 3. In addition to the performance, the Alpha's t-statistic, the number of observations, and the adjusted R-squared of the regressions are shown. The asterisks indicate significance at the 1%-level (***), 5%-level (**), and 10%-level (*).

Table 8: Annualized Performance of passive institutional and retail funds compared to their benchmark index

Table 8 shows the estimation of the performance of the groups of all passive funds, of all passive institutional funds, and of all passive retail funds compared to their corresponding benchmark index (benchmark portfolio). The performance is measured by the annualized Alpha from panel regressions of the Switzerland-specific Carhart (1997) model. The risk premiums for the size, value, and momentum factors are provided by Ammann and Steiner (2008). The Alphas are calculated for different time periods that are described in Table 3. In addition to the performance, the Alpha's t-statistic, the number of observations, and the adjusted R-squared of the regressions are shown. The asterisks indicate significance at the 1%-level (***), 5%-level (**), and 10%-level (*). The numbers for the institutional funds in the periods "Early" and "Bear" have to be interpreted with care as the samples are small.

Table 9: Annualized Performance of the ETFs and regression factor loadings compared to the SMI

Table 9 shows the estimation of the performance of the ETFs to their corresponding benchmark index (benchmark portfolio). The performance is measured by the annualized Alpha from panel regressions of the Switzerland-specific Carhart (1997) model. Data for the ETFs is available from April 2001 to March 2007. The risk premiums for the size, value, and momentum factors are provided by Ammann and Steiner (2008). The Alphas are calculated for the whole time period. In addition to the performance, the Alpha's t-statistic, the number of observations, the adjusted R-squared of the regressions, and the factor loadings and their t-statistics are shown. The asterisks indicate significance at the 1%-level (***), 5%-level (**), and 10%-level (*).

4.2 Active funds vs. index

Tables 10 and 11 further detail and validate the aggregated results for all active funds in Table 6. Though, for now we stay with the classical index-oriented performance measurement methodology. The performance of the active funds is measured for various subgroups and during different subperiods.

Table 10 breaks the performance of all active funds down into the groups of all active SPI-, SMI-, and SMC-funds, comparing each group to its corresponding index. We find interesting differences among the different subgroups. While active SPI- and SMI-funds underperform the index by a highly significant -2.0% p.a. and -2.6% p.a. respectively, the SMC-funds outperform the index by 2.0% p.a. As Table 10 Panel 2 shows, the alpha of the Small&Mid-Cap-funds is significantly higher than the one of SPI- and SMI-funds. These results support the hypothesis that the efficiency in the small- and mid-cap stock segment is substantially lower than in the large-cap segment, leading to this significantly higher alpha of Small&Mid-Cap-funds.

Another interesting observation from Table 10 is the significant superiority of the “Early” over the “Late” time period in the segment of SPI- and SMI-funds. Though, observation three from Table 6 (superior performance of “Early” vs. “Late” time period) is confirmed by Large-cap-funds. Increasing market efficiency in the large-cap segment could be at the origin of this result. The performance of SMC-funds did not substantially change from the “Early” to the “Late” time period. One potential reason for that could be that the growth of the listed Swiss Small&Mid-Cap-Companies from 1998 to 2000⁹ lead to additional return opportunities in this segment, compensating the efficiency increase.

Further, Table 10 shows that the SPI- and SMC-funds perform better in the “Bear” than in “Bull” period, while the SMI-funds perform better in the “Bull” period. Though the Bull-Bear-spread depends on the subgroup analysed. It seems to be likely that the results provided by Costa, Jakob, and Porter (2006) are not robust, but sensitive to the choice of the sample analysed. Observation four (superior performance of “Bear” vs. “Bull” time period) from Table 6 is strongly questioned though.

Finally, Table 11 shows one new finding: Active institutional funds perform better than active retail funds during all periods, although the difference is significant for the “Bull” period only. Active institutional funds perform even marginally better than their corresponding index. Further, Table 11 confirms above findings: Observations three (superior

performance of “Early” vs. “Late” time period) gets further support, whereas observation four (Bull-Bear-spread) is mixed for these two subgroups as well.¹⁰ This questions again the robustness of the results presented by Costa, Jakob, and Porter (2006).

Table 11 shows the estimation of the performance of the groups of all active funds, of all active institutional funds, and of all active retail funds compared to their corresponding benchmark index (benchmark portfolio). The performance is measured by the annualized Alpha from panel regressions of the Switzerland-specific Carhart (1997) model. The risk premiums for the size, value, and momentum factors are provided by Ammann and Steiner (2008). The Alphas are calculated for different time periods that are described in Table 3. In addition to the performance, the Alpha's t-statistic, the number of observations, and the adjusted R-squared of the regressions are shown. The last column of the table shows the differences of the alphas between institutional and retail funds, testing the significance of these differences by means of a t-test. The asterisks indicate significance at the 1%-level (***), 5%-level (**), and 10%-level (*).

4.3 Single funds vs. index

This section finishes the first part of the empirical section – which analyses the performance of passive and active funds in comparison to hypothetical indices – by providing the distribution of the alphas of the single funds. Table 12 shows the alphas of a comparison of the funds to their corresponding benchmark index. Table 13 presents the distribution of the corresponding factor loadings.

As expected, Table 12 shows that the weighted mean and the median of the distribution of the alphas are negative. The weighted mean is -0.26% p.a., which is close to the alpha of the panel regression of -0.4% p.a.¹¹ 47 or 29.4% of the 160 funds have a positive alpha, 113 a negative one. This percentage is slightly higher for active than for passive funds: from all active funds, 30.5% of the alphas are positive, whereas 21.1% of the alphas of the passive funds are positive. If the probability to beat the index would be the measure, still no clear statement on the superiority of active or passive investing would be possible. All institutional funds have 37.5% of positive alphas; all retail funds have 26.7% of positive alphas. Finally, there are only two out of the 160 funds that have a significantly positive alpha, whereas 24 or 15.0% of the alphas are significantly negative. In sum, Table 12 confirms earlier findings: Compared to hypothetical indices, the average alpha of the active and passive funds is negative. Additionally, there is still no clear picture whether active or passive funds perform better.

Table 13 confirms earlier findings as well. As in Table 5, the funds show a positive average factor loading for the size and the value factor, whereas the average factor loading of the momentum factor is negative. This confirms the preferences of Swiss equity fund managers to overweight small-cap, value, and low-momentum stocks in comparison to their benchmark.

¹¹ See Table 6, all funds, whole period.

Table 12: Annualized Performance of all single funds compared to their benchmark index

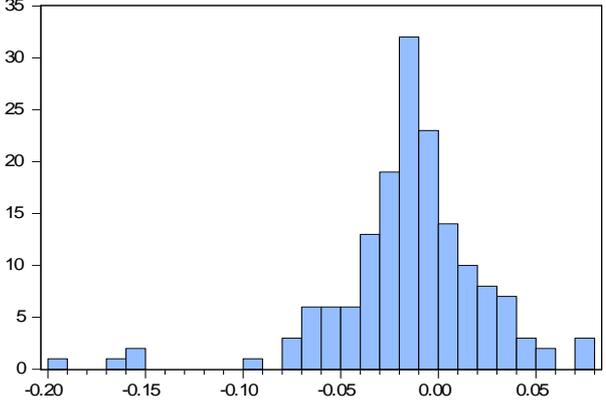

Panel 1: Descriptive statistics				
Distribution of Alphas (annualized)		Key ratios (annualized)		
		W. Mean	-0.26%	
		Median	-1.28%	
		Std. Dev.	3.91%	
		No. of funds	160	
Panel 2: Sign and significance of Alphas for different subgroups				
		All Funds	Active Funds	Passive Funds
All Funds	Number $\alpha+$	47	43	4
	Number $\alpha-$	113	98	15
	Number sign. $\alpha+$	2	2	0
	Number sign. $\alpha-$	24	20	4
All Institutional Funds	Number $\alpha+$	15	13	2
	Number $\alpha-$	25	19	6
	Number sign. $\alpha+$	2	2	0
	Number sign. $\alpha-$	5	3	2
All Retail Funds	Number $\alpha+$	32	30	2
	Number $\alpha-$	88	79	9
	Number sign. $\alpha+$	0	0	0
	Number sign. $\alpha-$	19	17	2

Table 12 shows the results of the estimation of the performance of all single funds compared to their corresponding benchmark index (benchmark portfolio). The performance is measured for each fund by the annualized Alpha from regressions of the Switzerland-specific Carhart (1997) model. The risk premiums for the size, value, and momentum factors are provided by Ammann and Steiner (2008). Panel 1 presents the descriptive statistics of the sample of the 160 alphas (Graph, Weighted Mean (with no. of observations), Median, Standard deviation, number of funds). Panel 2 shows the number of positive (Number $\alpha+$), negative (Number $\alpha-$), significantly positive (Number sign. $\alpha+$), and significantly negative (Number sign. $\alpha-$) alphas for all funds as well as for the subgroups of the active, passive, institutional, and retail funds. Significance is tested at the 5%-level.

Table 13: Distribution of the factor loadings of all single funds

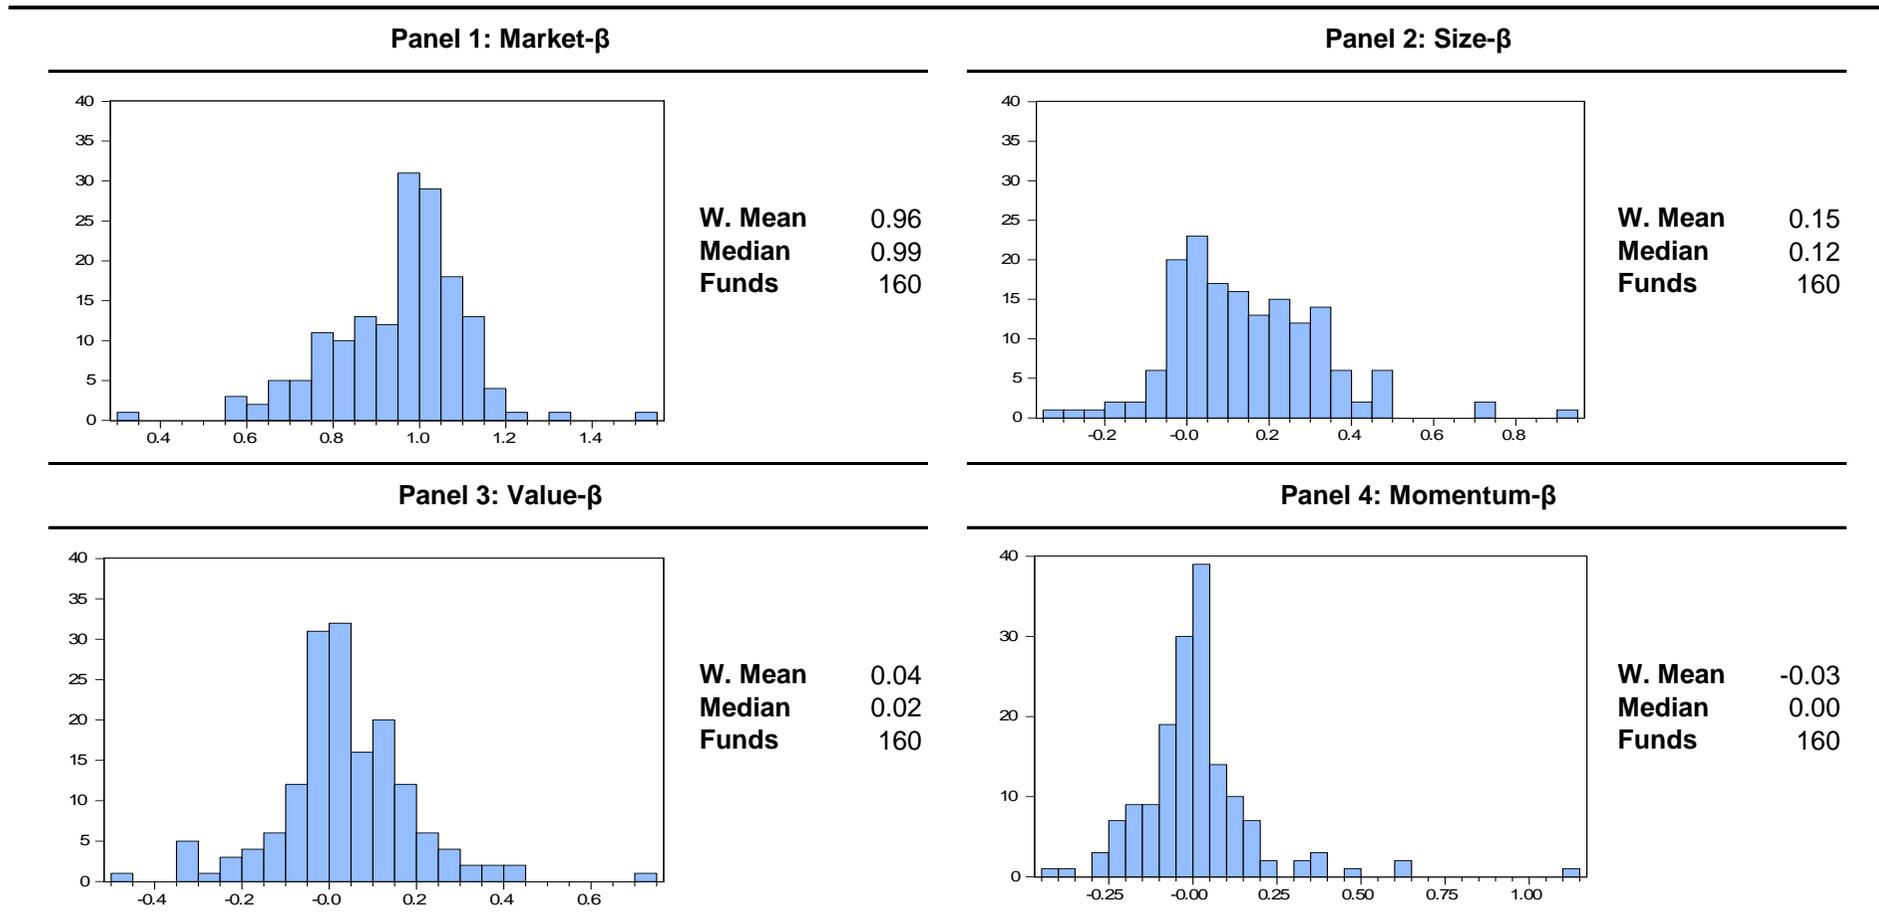

Table 13 shows the market, size, value, and momentum factor loadings of the estimation of the performance of all single funds compared to their corresponding benchmark index (benchmark portfolio). The performance and the factor loadings are estimated by means of the Switzerland-specific Carhart (1997) model. The risk premiums for the size, value, and momentum factors are provided by Ammann and Steiner (2008). The Panels present the descriptive statistics for the four factor loadings from the regressions of the 160 funds (Graph, Weighted Mean (with no. of observations), Median, number of funds).

In sum, the first part – comparing active and passive funds to indices – provides six key findings: First, active and passive funds significantly underperform indices on an aggregated basis. However, the subgroup of the active Small&Mid-Cap- funds is the exception from this result: They show a significant outperformance in comparison to their corresponding index. Second, no statement about the superiority of active or passive investing is possible. Third, active funds perform better in the “Early” than in the “Late” time period, which could be due to increased market efficiency. Passive funds, however, show stable performance during the “Early” and the “Late” time period. Fourth, there is no robust structure with respect to the differential between the performance during the “Bull” and the “Bear” period. Although in the aggregated samples it seems that the findings of Costa, Jakob, and Porter (2006) are confirmed, further analysis showed that this result is not robust, but sensitive to the choice of the subgroup.¹² Fifth, the factor loadings show that the average manager of an active Swiss equity fund overweights small-cap, value, and low-momentum stocks in comparison to the benchmark. Sixth, all our prior findings suggest that institutional funds perform better than retail funds.

The following sections will mainly dig deeper into the second observation concerning the direct comparison of active and passive funds. Active funds will be directly put side by side with passive funds. However, the reader has to keep in mind that the comparability of the following results with the findings above is difficult as the following sections directly compare active and passive funds. Up to now, active and passive funds had the same reference (their corresponding index), whereas in the following parts, active and passive funds will be directly compared to each other. Though, various characteristics of active and passive funds will be mixed.¹³

4.4 Active funds vs. passive funds

A fair judgement on the performance of active funds is only possible if they are compared directly to passive investment funds. Passive investment funds are investable instruments after costs, whereas indices are hypothetical, cost-free constructs. For this reason, this and the following section directly compare active to passive funds by means of the methodology described above.

¹² Costa, Jakob, and Porter (2006) find that US equity funds perform better in bear-markets than in bull-markets.

¹³ For example, in the next sections the difference of the “Early” to the “Late” and of the “Bear” to the “Bull” period is a result of the above differences for active and passive funds. If both active and passive funds perform better in “Bear” than in “Bull” markets when comparing them to their corresponding indices, the direct comparison of active and passive funds could show no effect as the two effects compensate each other.

Table 14 starts with the evaluation of all active funds, all active SPI-funds, all active SMI-funds, and all active Small&Mid-Cap-funds, compared to the corresponding set of passive funds as benchmark portfolio. Active SPI-funds are compared to the passive SPI-funds, active SMI-funds to the passive SMI-funds, and active SMC-funds to the passive SMC-fund. The aggregated sample of all active funds underperforms the corresponding passive funds by a highly significant -1.1% p.a. Active SPI- and SMI-funds both underperform passive funds by a highly significant -1.4% p.a. and -1.9% p.a. respectively. By contrast, the active Small&Mid-Cap-funds perform well. The alpha in comparison to the passive fund is positive and highly significant. As the t-statistics in Table 14 Panel 2 confirm, the performance of active Small&Mid-Cap-funds is significantly better than the one of SPI- and SMI-funds. A possible explanation for the good performance of Small&Mid-Cap-funds is the lower efficiency in this market segment compared to the large-cap segment. However, as there is only one passive fund with just 27 observations these results for the Small&Mid-Cap-funds have to be interpreted with care. This limited sample size imposes considerable restrictions on the informative value of the comparison of active to passive Small&Mid-Cap-funds. For that reason, we continue the comparison of active to passive funds with a focus on the SPI- and SMI-funds.

For different subperiods, we find again that active SPI- and SMI-funds performed significantly better in the “Early” than in the “Late” time period, perhaps indicating increased market efficiency in the “Late” period. The performance in bull- and bear-markets is mixed once more.

One result from Table 14 requires further explanation. In Table 6, all active funds had a smaller underperformance compared to the corresponding indices (-0.4% p.a.) than all passive funds (-0.8% p.a.). Due to that, it seems surprising that the direct comparison of all active funds to the passive funds leads to a highly significant underperformance of the active funds of -1.1% p.a. Intuitively, the reader would expect that the underperformance decreases when comparing active funds to passive funds instead of comparing them to an index. However, this result has a good reason: Changing from indices to passive funds as benchmark portfolios, the number of observations decreases as we have fewer observations for passive funds than for indices. Appendix 1 shows in detail that this shrinkage of observations leads to a decline of the performance, overcompensating the observed and expected increase of the alpha from the isolated change from indices to passive funds. This result in Table 14 is therefore consistent with the result from Table 6.

Table 14, Panel 1: Annualized Performance of active, benchmark-grouped funds compared to the benchmark portfolio of all corresponding passive funds

Table 14, Panel 1 shows the estimation of the performance of the groups of all active funds, of all active SPI-funds, of all active SMI-funds, and of all active SMC-funds (Small&Mid-Cap-funds) compared to all corresponding passive funds (equally-weighted benchmark portfolio). All active funds are compared to a benchmark portfolio of all corresponding passive funds, active SPI-funds to a benchmark portfolio of passive SPI-funds, active SMI-funds to a benchmark portfolio of passive SMI-funds, and active SMC-funds to a passive SMIM-fund. The performance is measured by the annualized Alpha from panel regressions of the Switzerland-specific Carhart (1997) model. The risk premiums for the size, value, and momentum factors are provided by Ammann and Steiner (2008). The Alphas are calculated for different time periods that are described in Table 3. In addition to the performance, the Alpha's t-statistic, the number of observations, and the adjusted R-squared of the regressions are shown. The asterisks indicate significance at the 1%-level (***), 5%-level (**), and 10%-level (*).

Table 14, Panel 2: Differences of annualized performances of various subgroups and subperiods of active funds compared to corresponding passive funds

Table 14, Panel 2 shows the estimation of the differences of the performances of the subgroups from Table 14, Panel 1. The Alpha in Panel 1 is measured by the annualized Alpha from panel regressions of the Switzerland-specific Carhart (1997) model. This Panel shows the differences of the alphas between different subgroups and time periods as well as the significance of these differences, tested by means of a t-test. The asterisks indicate significance at the 1%-level (***), 5%-level (**), and 10%-level (*).

	Adj. R-squared	0.83	0.82	0.83	-

Table 15 shows the estimation of the performance of the groups of all active funds, of all active institutional funds, and of all active retail funds compared to all corresponding passive funds (equally-weighted benchmark portfolio). All active funds are compared to the benchmark portfolio of all passive funds, all active institutional funds are compared to the benchmark portfolio of all passive institutional funds, and all active retail funds are compared to the benchmark portfolio of all passive retail funds. The performance is measured by the annualized Alpha from panel regressions of the Switzerland-specific Carhart (1997) model. The risk premiums for the size, value, and momentum factors are provided by Ammann and Steiner (2008). The Alphas are calculated for different time periods that are described in Table 3. In addition to the performance, the Alpha's t-statistic, the number of observations, and the adjusted R-squared of the regressions are shown. The last column of the table shows the differences of the alphas between institutional and retail funds, testing the significance of these differences by means of a t-test. The asterisks indicate significance at the 1%-level (***), 5%-level (**), and 10%-level (*).

Table 15 continues our analysis with the comparison of all active institutional funds and all active retail funds to the corresponding passive funds. We find that active institutional funds underperform passive funds by a statistically not significant -0.1% p.a., whereas active retail funds underperform passive funds by a highly significant -1.2% p.a. Further, the alpha of the active institutional funds is higher than the alpha of the active retail funds with significance at the 10%-level.

4.5 Active SPI-, SMI- and Small&Mid-Cap-funds vs. passive funds

Finally, in Tables 16 to 18 we look into the subgroups of the active institutional and retail SPI-, SMI-, and SMC-funds by comparing them to corresponding benchmark portfolios of passive funds. These final evaluations have to be interpreted with care for three reasons: First, the samples get smaller. Second, there are time periods where we have a lack of data for the active funds or the corresponding benchmark portfolio. Third, the findings are a mixture of effects resulting from the performance of active funds and of passive funds.

Tables 16 to 17 confirm that active SPI- and SMI-funds generally underperform their passive equivalents. However, these tables show as well that the performance of institutional and retail funds depends strongly on the subgroup analysed. While active institutional SPI-funds have a performance insignificantly different from passive SPI-funds (-0.4% p.a.), active institutional SMI-funds underperform passive SMI-funds by a highly significant -4.5% p.a. The picture is less differentiated for active retail SPI- and SMI-funds. Both active retail SPI- and SMI-funds underperform their passive counterparts by a significant -1.5% p.a. The results for the SMC-funds compared to the passive fund – we highlight again the limited informative value for this comparison due to just one passive fund with 27 observations only – are similar as for their comparison to the index: They significantly outperform compared to the passive benchmark portfolio.

In sum, the second part (Tables 14 to 18) – directly comparing actively managed funds to benchmark portfolios of passively managed funds – allows differentiated statements on the performance of actively managed Swiss equity funds. First, actively managed funds significantly underperform passively managed funds by -1.1% p.a. on an aggregated basis. However, this result depends strongly on the subgroup analysed: Active SPI- and SMI-funds both significantly underperform. By contrast, the active Small&Mid-Cap-funds have a positive alpha. Additionally, the risk-adjusted performance of active Small&Mid-Cap-funds is significantly better than the performance of active SPI- and SMI-funds. Second, this part

confirms again that – on an aggregated basis – institutional Swiss equity funds perform better than retail funds. However, this result depends on the subgroup analysed as well: It is true for active SPI- and SMC-funds, but does not hold for active SMI-funds.

Table 16: Annualized Performance of active institutional and retail SPI-Funds compared to the benchmark portfolio of all passive SPI-Funds

	Observations	1'020	336	684
	Adj. R-squared	0.83	0.88	0.81

Table 18 shows the estimation of the performance of the groups of all active Small&Mid-Cap-Funds, of all active institutional Small&Mid-Cap-Funds, and of all active retail Small&Mid-Cap-Funds compared to the passive SMIM-Fund (benchmark portfolio). The performance is measured by the annualized Alpha from panel regressions of the Switzerland-specific Carhart (1997) model. The risk premiums for the size, value, and momentum factors are provided by Ammann and Steiner (2008). The Alphas are calculated for different time periods that are described in Table 3. In addition to the performance, the Alpha's t-statistic, the number of observations, and the adjusted R-squared of the regressions are shown. The asterisks indicate significance at the 1%-level (***), 5%-level (**), and 10%-level (*). However, the results have to be interpreted with care as there is only one passive SMC-fund with only 27 observations.

5. Conclusion

This study analyses the risk-adjusted performance of 160 actively and passively managed mutual funds investing in Swiss stocks between 1989 and 2007. Our contribution to the existing literature is threefold: First, we substantially extend the scarce research on the performance of Swiss equity funds by applying an advanced performance measurement methodology, by analysing a larger sample with a reduced survivorship bias, by analysing factor loadings and by checking the performance and the robustness of the results in different subgroups and subperiods. Second, we are directly comparing actively and passively managed Swiss equity funds, thereby applying a Switzerland-specific Carhart (1997) model. Third, we analyse the performance of passive Swiss equity funds. To the best of our knowledge, we are the first to compare the performance of active Swiss equity funds not only to a theoretical index, but also to passive index funds, to apply the mentioned methodology to compare active and passive funds, and to analyse the performance of passive Swiss equity funds.

We find that on average passive Swiss equity funds significantly underperform indices by -0.8% p.a. Further, our analysis confirms that in general active funds underperform indices. By analysing various subgroups, we find that both active SPI- and SMI-funds significantly underperform their corresponding indices by -2.0% p.a. and -2.6% p.a. respectively. The exception is the subgroup of the active Small&Mid-Cap-funds showing a significantly positive risk-adjusted performance in comparison to their corresponding index of 2.0% p.a. We think that the superior performance of Small&Mid-Cap-funds is an indication of lower market efficiency in this segment in comparison to the large-cap segment. Consequently, we conclude that in the Swiss stock market it is worth actively managing Small&Mid-Cap investments, while the high market efficiency favours passive investments in the large-cap segment. Further, the factor loadings of the Switzerland-specific Carhart (1997) model show that the average manager of an active Swiss equity fund systematically overweights small-cap, value, and low-momentum stocks in comparison to the benchmark.

When directly comparing active to passive Swiss equity funds, we find a significant underperformance of the active funds of -1.1% p.a. on an aggregated basis. However, the results are mixed for different subgroups, confirming the findings resulting from the comparison to indices: Active SPI- and SMI-funds both significantly underperform, while active Small&Mid-Cap-funds have a significantly positive alpha. However, the informative value of this particular result for Small&Mid-Cap-funds is limited because of the small number of observations for the passively managed benchmark funds.

Finally, we analyse different subperiods. We find that active funds perform better before the millennium than thereafter, while passive funds show no respective performance differential. This robust result supports the hypothesis of ongoing efficiency increases in the stock market, making active fund management more challenging from the performance perspective. Further results that the finding of earlier studies – saying that active equity mutual funds perform better in bear- than in bull-markets – is not robust, but most probably due to a random sample selection. Our analysis reveals that the spread between bull- and bear-market-alphas is sensitive to the subgroup and subperiod analysed.

Appendix 1

Table A1 shows that the aggregated performance of all active funds in Tables 6, 10, and 11 (*indices as benchmark portfolios*, column 1 in Table A1) is consistent with the performance of all active funds in Tables 14 and 15 (*passive funds as benchmark portfolios*, column 3 in Table A1). Table A1 demonstrates that by decomposing the change of the benchmark portfolio (from corresponding indices to corresponding passive funds) into the two comprised steps, both influencing the change of the alpha.

The first step (from column 1 to 2 in Table A1) is the reduction of observations, resulting from lower data availability for passive funds than for indices. This effect has been isolated in the first step through changing the sample size only, but not the benchmark portfolio. As Table A1 shows, this effect further decreases the alpha. This is due to the fact that mainly the observations from the SMC-funds and the Early time period, both comparably good performing subgroups, are affected by this data shrinkage.

The second step (from column 2 to 3 in Table A1) is the change of the benchmark portfolio from corresponding indices to corresponding passive funds (with fixed observations). As expected, Table A1 shows that this effect decreases the underperformance.

By merging steps one and two – both causing explainable changes of the alphas – there results an intuitively unexpected, but well explainable decrease of the alpha (from column 1 to 3 in Table A1).

Our further analysis not reported here showed that the same effect is causing the decrease of the aggregated alpha of all active retail funds. Changing the benchmark portfolio from the corresponding indices (Table 11) to the corresponding passive funds (Table 15), the decrease of the alpha resulting from the reduction of observations (step 1) overcompensates the increase of the alpha from the isolated change of the benchmark portfolio (step 2).

Table A1: Annualized Performance of all active funds compared to the corresponding indices and passive funds, dependent on data availability for indices and passive funds

Table A1 shows the estimation of the performance of all active funds compared to different benchmark portfolios. The first column shows the results of all active funds being compared to the corresponding indices (benchmark portfolios). In the second column, the data for the indices (benchmark portfolios) are limited to the data points where data on passive funds are available. The third column finally shows the results of all active funds being compared to the corresponding passive funds (benchmark portfolios). The performance is measured by the annualized Alpha from panel regressions of the Switzerland-specific Carhart (1997) model. The risk premiums for the size, value and momentum factors are provided by Ammann and Steiner (2008). The Alphas are calculated for different time periods that are described in Table 4. In addition to the performance, the Alpha's t-statistic, the number of observations and the adjusted R-squared of the regressions are shown. The asterisks indicate significance at the 1%-level (***), 5%-level (**), and 10%-level (*).
